DaimlerChrysler AG

Patent Claims

- Control of an electric motor which can be switched 5 1. between the motor mode and the generator mode, coupled or can be coupled to an internal combustion engine and has an associated battery, in particular in a hybrid drive (1) with an internal combustion engine 10 (2) and an electric motor (3) which can be switched between the generator mode and the motor mode, as well as a battery (6), which is associated with the electric motor and has a sensor system which records its state of charge, in which case the internal combustion engine and the electric motor are coupled and/or can 15 coupled to the output drive (5) of the hybrid drive for drive purposes, and the electric motor can be driven by the internal combustion engine and/or the output drive
- 20 characterized

during the generator mode,

in that, during operating phases in which the internal combustion engine is operating and is coupled to the output drive, the electric motor operates

- predominantly in the generator mode only when the load on the internal combustion engine is low, and/or
 - predominantly in the motor mode when the load on the internal combustion engine is high.
- 30 2. Control as claimed in claim 1, characterized

in that data for changes which occur in the fuel consumption of the internal combustion engine (2) which occur in the event of load changes can be recorded as a function of the rotation speed of the internal

function of the rotation speed of the internal combustion engine (2), and/or are stored, and the electric motor (3)

- is operated as a generator when the quotient of the load change and the consumption change exceeds a first threshold value and/or
- 5 is operated as a motor when the quotient of the load change and the consumption change of the internal combustion engine is less than the abovementioned threshold value or a second threshold value.

3. Control as claimed in claim 1 or 2, characterized

in that the electric motor is operated with increasing generator power when the quotient of the load change and the consumption change of the internal combustion engine increases.

- 4. Control as claimed in one of claims 1 to 3, characterized
- in that the electric motor is operated with increasing motor power when the quotient of the load change and consumption change of the internal combustion engine falls.
- 25 5. Control as claimed in one of claims 1 to 4, characterized

in that, if the electric motor (3) is continuously positively coupled to the output drive (5), the electric motor always operates either in the motor mode or in the generator mode.
